

A Small Study of Reliable Translation

AcademicPDFTranslator contributors | Synthetic test paper

Abstract

We study reliable translation of scientific documents.
The method preserves measurements, references, and technical symbols.
It achieves a recall of 0.873 at 5% coverage [23].

1 Introduction

Domain alignment alone cannot guarantee target-domain discriminability.
This limitation motivates a separate check of numerical consistency.

The FPGA operates at 300 MHz and uses 128 samples.
Fig. 3 compares S21 with the baseline. Table IV reports the results.

Fig. 3. A synthetic caption for the translation pipeline.

2 Method

We protect each scientific token before requesting a translation.
A deterministic checker then compares the restored values.

3 Results

The left column starts here.
Recall reaches 0.873 [12].
The first experiment uses 128 samples.

The right column follows the left.
Fig. 3 summarizes the experiment.
The baseline uses 256 samples.

A second experiment tests the FPGA.
It operates at 300 MHz.
The measured coverage is 98.2%.

A limitation is the small sample size.
The checker does not verify meaning.
Human review remains necessary.

Table IV. Synthetic measurement results.

4 Conclusion

Preserving scientific tokens makes translation errors easier to inspect.
This fixture demonstrates extraction and checks, not model quality.
